# Preface

# Chapter 1

## Runtime Analysis

*Algorithms* are any well-defined computational procedures that take some value(s) as input and produce more value(s) as output. They are **effective**, **precise**, and **finite**. There are several ways to analyze the runtime of an algorithm.

### 1.1 Power Law

1. For the algorithm, get a table for the input size  $n$  and the runtime  $T(n)$ .

$n$	$T(n)$
250	0.0
500	0.012
1000	0.0954
2000	0.7727
4000	6.1664

2. Make sure that the data plots:

- **have enough data plots.** For instance, if there are only two data plots, you should not make the power law conjecture.
- **fits the power law.** You can verify this by finding the ratio between data plots.

$n$	$T(n)$	ratio
250	0.0	–
500	0.012	–
1000	0.0954	$0.0954 / 0.012 = 7.95$
2000	0.7727	$0.7727 / 0.0954 = 8.10$
4000	6.1664	$6.1664 / 0.7727 = 7.98$

For the ratios we found, //TODO

### 1.2 Runtime Expressions

### 1.3 Asymptotic Runtime Analysis

### 1.4 Recursive Relationship

# Chapter 2

## Intro to Data Structures

*Data structures* are collections of data values, the relationships among them, and the functions or operations that can be applied to the data. All three characteristics need to be present.

### 2.1 Array

*Array* is a linear container of items.

Array length 6	250	251	252	253	254	255
	0	1	2	3	4	5

- Access time:  $\Theta(1)$
- Inserting  $n$  items in the *tail* for array size  $n$ :  $\Theta(1)$  per item,  $n \times \Theta(1) \in \Theta(1)$
- Inserting  $n$  items in the *tail* for array size *unknown*:  $\Theta(n)$  per item,  $n \times \Theta(n) \in \Theta(n)$

Lesson? **Keep track of the tail!**

### 2.2 Linked List

### 2.3 Stack

### 2.4 Queue

### 2.5 Binary Heap

#### 2.5.1 Building a Heap – Top-down v.s. Bottom-up

### 2.6 Tree

## Chapter 3

# Sorting Algorithms

Once you store all the items in a data structure, you might want to organize them for the future use (such as selecting  $n$ th largest element). For this, you have to *sort* the data structure (in this book, array will be assumed). *Sorting* is deciding how to permute the array elements until they are sorted.

There are couple aspects of sorting algorithms you need to consider:

- **Runtime:** When analyzing a runtime of a sorting algorithm, both number of compares and number of swaps are considered. **Most sorting algorithms make more compares than swaps**, but if a sorting algorithm makes more swaps, it must be used for the asymptotic runtime analysis
- **Stability:** An algorithm is stable if it preserves the input ordering of equal items.

unsorted list	<table><tr><td>5</td><td>3</td><td>5'</td><td>2</td><td>7</td></tr></table>	5	3	5'	2	7
5	3	5'	2	7		
sorted with stable sorting algorithm	<table><tr><td>2</td><td>3</td><td>5</td><td>5'</td><td>7</td></tr></table>	2	3	5	5'	7
2	3	5	5'	7		
sorted with unstable sorting algorithm	<table><tr><td>2</td><td>3</td><td>5'</td><td>5</td><td>7</td></tr></table>	2	3	5'	5	7
2	3	5'	5	7		

- **In-place:** An algorithm is in-place if it can directly sorts the items without making a copy or extra array(s)

### 3.1 Bubble, Selection, Insertion Sort

The first three sorting algorithms we will discuss are BUBBLE-SORT, SELECTION-SORT, and INSERTION-SORT. They are simple to understand and implement, however, they all have the worst case runtime of  $O(n^2)$ , which limits their uses.

BUBBLE-SORT goes through the array and swap elements that are out of place, and if such element is found, it repeats from the beginning.

```
1: function BUBBLE-SORT( $A$ )
2:    $repeat \leftarrow \text{True}$ 
3:   while  $repeat$  is  $\text{True}$  do
4:      $repeat \leftarrow \text{False}$ 
5:     for  $i = 0$  to  $n - 2$  do
6:       if  $A[i] > A[i + 1]$  then
7:          $\text{SWAP}(A, i, i + 1)$ 
8:        $repeat \leftarrow \text{True}$ 
9:   return  $A$ 
```

▷  $A$  is an array size  $n$

▷ Assume  $\text{SWAP}(A, i, j)$  swaps  $A[i]$  and  $A[j]$

In-place?	Stable?
True	True

-	NumCompares	NumSwaps
Already Sorted	$n - 1$	0
Worst Case	$n^2 - n$	$\frac{1}{2}n^2 - \frac{1}{2}n$

SELECTION-SORT is a sorting algorithm closest to our “natural” thought of sorting an array. It makes the same number of comparisons no matter what.

---

```

1: function SELECTION-SORT( $A$ )                                      $\triangleright A$  is an array size  $n$ 
2:   for  $i = 0$  to  $n - 2$  do
3:      $index \leftarrow i$ 
4:     for  $i = i + 1$  to  $n - 1$  do
5:       if  $[j] < A[index]$  then
6:          $index \leftarrow j$ 
7:     if  $i \neq index$  then
8:        $SWAP(A, i, index)$                                         $\triangleright$  Assume  $SWAP(A, i, j)$  swaps  $A[i]$  and  $A[j]$ 
9:   return  $A$ 

```

---

In-place?	Stable?
True	False

-	NumCompares	NumSwaps
Already Sorted	$\frac{1}{2}n^2 - \frac{1}{2}n$	0
Worst Case	$\frac{1}{2}n^2 - \frac{1}{2}n$	$\lfloor \frac{1}{2}n \rfloor$

INSERTION-SORT, as the name suggests, take one element at a time and swaps it until it's at the correct index.

---

```

1: function INSERTION-SORT( $A$ )                                      $\triangleright A$  is an array size  $n$ 
2:   for  $i = 1$  to  $n - 1$  do
3:      $j \leftarrow i - 1$ 
4:     while  $j \geq 0$  and  $A[j] > A[j + 1]$  do
5:        $SWAP(A, j, j + 1)$                                         $\triangleright$  Assume  $SWAP(A, i, j)$  swaps  $A[i]$  and  $A[j]$ 
6:        $j \leftarrow j - 1$ 
7:   return  $A$ 

```

---

In-place?	Stable?
True	True

-	NumCompares	NumSwaps
Already Sorted	$n - 1$	0
Worst Case	$\frac{1}{2}n^2 - \frac{1}{2}n$	$\frac{1}{2}n^2 - \frac{1}{2}n$

## 3.2 Shell Sort

SHELL-SORT runs insertion sort with “gaps”, the index margin where insertion sort will be performed.

---

```

1: function SHELL-SORT( $A, H$ )                                      $\triangleright A$  is an array size  $n$ ,  $H$  is the array size  $m$  containing gap values

```

---

---

```

2:  for  $h = 0$  to  $m - 1$  do
3:       $gap \leftarrow H[h]$ 
4:      for  $i = 1$  to  $n - 1$  do
5:           $j \leftarrow i - 1$ 
6:          while  $j \geq 0$  and  $j + gap < n$  do
7:              if  $A[j] > A[j + gap]$  then
8:                   $SWAP(A, j, j + gap)$ 
9:               $j \leftarrow j + gap$ 
10: return  $A$ 

```

---

### 3.3 Heap Sort

HEAP-SORT uses binary max-heap to sort an array. While it's the first sorting algorithm to utilize a data structure, it's not preferred in real life due to cache issue.

---

```

1: function HEAP-SORT( $A$ )  $\triangleright A$  is an array size  $n$ 
2:    $A \leftarrow \text{BUILD-HEAP}(A)$ 
3:   for  $i = n - 1$  down to  $0$  do
4:        $\text{SORT-DOWN}(A, i)$ 
5:   return  $A$ 

```

---

The algorithm first builds the heap from the array elements (refer to section 2.5 for methods for building a heap). BOTTOM-UP is used for its runtime. Then the algorithm calls SORT-DOWN from the last heap elements down to the first.

#### 3.3.1 Sort Down Algorithm

### 3.4 Merge Sort

MERGE-SORT is an algorithm //TODO

---

```

1: function MERGE-SORT( $A, l, r$ )  $\triangleright A$  is an array size  $n$ 
2:   if  $l < r$  then
3:        $m \leftarrow (l + r) / 2$ 
4:       MERGE-SORT( $A, l, m$ )
5:       MERGE-SORT( $A, m + 1, r$ )
6:       MERGE( $A, l, m, r$ )
7:   return  $A$ 

```

---

#### 3.4.1 Merge Algorithm

```

.....
1: function MERGE( $A, l, m, r$ )  $\triangleright A$  is an array size  $n$ 
2:    $n1 \leftarrow m - l + 1$ 
3:    $n2 \leftarrow r - m$ 
4:    $L \leftarrow$  array size of  $(n1 + 1)$ 
5:    $R \leftarrow$  array size of  $(n2 + 1)$ 
6:    $\triangleright$  Assign elements to each array  $\triangleleft$ 
7:   for  $i = 0$  to  $n1 - 1$  do
8:        $L[i] \leftarrow A[l + i]$ 

```

---

```

9:   for  $i = 0$  to  $n2 - 1$  do
10:  |    $R[i] \leftarrow A[m + j + 1]$ 

11:   $L[n1], R[n2] \leftarrow \infty$ 
12:   $i, j \leftarrow 0$ 

13:  for  $k = l$  to  $r$  do
14:  |   if  $L[i] \leq R[j]$  then
15:  |   |    $A[k] \leftarrow L[i]$ 
16:  |   |    $i \leftarrow i + 1$ 
17:  |   else
18:  |   |    $A[k] \leftarrow R[j]$ 
19:  |   |    $j \leftarrow j + 1$ 
20:  |   return  $A$ 

```

.....

## 3.5 Quick Sort

QUICK-SORT is another divide-and-conquer sorting algorithm.

---

```

function QUICK-SORT( $A, l, r$ )                                     ▷  $A$  is an array size  $n$ 
|   if  $l < r$  then
|   |    $m \leftarrow \text{PARTITION}(A, l, r)$ 
|   |   QUICK-SORT( $A, l, m - 1$ )
|   |   QUICK-SORT( $A, m + 1, r$ )
|   return  $A$ 

```

---

### 3.5.1 Partition and Pivot

---

```

function PARTITION( $A, l, r$ )                                     ▷  $A$  is an array size  $n$ 
|    $p = A[r]$ 
|    $i = l - 1$ 
|   for  $j = 1$  to  $r$  do
|   |   if  $A[j] < p$  then
|   |   |    $i \leftarrow i + 1$ 
|   |   |   SWAP( $A, i, j$ )
|   |    $i \leftarrow i + 1$ 
|   |   SWAP( $A, i, r$ )
|   return  $i$ 

```

---

## 3.6 Decision Tree and the Lower Bound for Comparison Sorting Algorithm

So far, we have been discussing *comparison sorting algorithms* (sorting algorithms that only reads array elements through  $>, =, <$  comparison). We can draw a decision tree with all the permutations of how a comparison sorting algorithms would compare and sort the array  $[a_0, a_1, a_2]$ .

The decision tree for array size of 3 has  $3! = 6$  leaves, and it is trivial that a decision tree for an **array with  $n$  elements will have  $n!$  leaves**. The height of the decision tree represents the worst-case number of comparisons the algorithm has to make in order to sort the array.

A tree with the height  $h$  has at most  $2^h$  leaves. Using this property, we can have the lower Big-omega bound for height of the decision tree for comparison sorting algorithms.

$$\begin{aligned}
 2^h &\geq n! \therefore h \geq \log_2(n!) && (h \text{ is the height of the decision tree}) \\
 h &\geq \log_2(n!) = \log_2(1 \cdot 2 \cdot \dots \cdot (n-1) \cdot n) \\
 &= \log_2(1) + \log_2(2) + \dots + \log_2(n-1) + \log_2(n) \\
 &= \sum_{i=1}^n \log_2(i) = \sum_{i=1}^{\frac{n}{2}-1} \log_2(i) + \sum_{i=\frac{n}{2}}^n \log_2(i) \\
 &\geq 0 + \sum_{i=\frac{n}{2}}^n \log_2(i) \geq 0 + \sum_{i=\frac{n}{2}}^n \log_2\left(\frac{n}{2}\right) && (i \text{ in the former expression is } \geq \frac{n}{2}) \\
 &= \frac{n}{2} \log_2\left(\frac{n}{2}\right) && (i = \frac{n}{2} \text{ to } n \text{ is exactly } \frac{n}{2} \text{ iterations}) \\
 &\in \Theta(n \log_2(n))
 \end{aligned}$$

Because  $h \geq \log_2(n!) \in \Theta(n \log_2(n))$ ,  $h \in \Omega(n \log_2(n))$ . Therefore, we can conclude that any **comparison sorting algorithms cannot run faster than  $O(n \log_2(n))$  time** in the worst-case scenario.

### 3.7 Bucket Sort

BUCKET-SORT is a sorting algorithm where elements are divided into each "bucket" and a different sorting algorithm is called for each bucket. While BUCKET-SORT is a comparison sorting algorithm, it's an attempt to reduce the runtime by decreasing the number of elements that the sorting algorithm has to sort.

### 3.8 Counting Sort

COUNTING-SORT is a *non-comparison* sorting algorithm. It uses the extra array *count*, where its index initially represents the value of each element in *A* (e.g., if there are three 5's in *A*,  $count[5] = 3$  before the "accumulation" step to determine the final index), to sort the array.

---

<pre> 1: <b>function</b> COUNTING-SORT(<i>A</i>, <i>k</i>) 2:   <i>count</i> <math>\leftarrow</math> array size <i>k</i> + 1 filled with 0 3:   <b>for</b> <i>i</i> = 0 to <i>n</i> - 1 <b>do</b> 4:     <i>count</i>[<i>A</i>[<i>i</i>]] <math>\leftarrow</math> <i>count</i>[<i>A</i>[<i>i</i>]] + 1  5:   <b>for</b> <i>i</i> = 1 to <i>k</i> <b>do</b> 6:     <i>count</i>[<i>i</i>] <math>\leftarrow</math> <i>count</i>[<i>i</i>] + <i>count</i>[<i>i</i> - 1]</pre>	<p><math>\triangleright A</math> is an array size <math>n</math>, <math>k</math> is the max element of <math>A</math></p> <p><math>\triangleright</math> Num occurrence in each element in <math>A</math>, <math>O(n)</math></p> <p><math>\triangleright</math> Accumulate the values in <i>count</i> from left to right, <math>O(k)</math></p>
----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

---

```

7:  out ← array size n
8:  for i = n - 1 down to 0 do      ▷ Use count values to determine the index for the elements in A, O(n)
9:      out[count[A[i]] - 1] ← A[i]
10:     count[A[i]] ← count[A[i]] - 1
11: return out

```

1. Suppose we have an array  $A = [2, 5, 3, 0, 2, 3, 0, 3]$ .  $k = \text{MAX}(A) = 5$ .
2. Initialize *count*, the array size  $5 + 1$ , with 0's.  $\text{count} = [0, 0, 0, 0, 0, 0]$ .
3. Count number of occurrence.  $\text{count} = [2, 0, 2, 3, 0, 1]$  (e.g., 2 occurred 2 times)
4. Accumulate values of *count* from left to right.  $\text{count} = [2, 2, 4, 7, 7, 8]$  (e.g.,  $\text{count}[1] = 2 + 0$ ,  $\text{count}[2] = 2 + 0 + 2$ , ...)
5. Initialize *out*, the array size  $n = 8$ , with nil's.  $\text{out} = [\text{nil}, \text{nil}, \text{nil}, \text{nil}, \text{nil}, \text{nil}, \text{nil}, \text{nil}]$ .
6. Place each element to the *out* array using *count* array
  - (a) When  $i = n - 1 = 7$ :  $A[7] = 3$  and  $\text{count}[3] = 7 \Rightarrow \text{out}[7 - 1] := A[7] = 3$  and  $\text{count}[3] := 7 - 1$   
 $\text{out} = [\text{nil}, \text{nil}, \text{nil}, \text{nil}, \text{nil}, \text{nil}, 3, \text{nil}]$   
 $\text{count} = [2, 2, 4, 6, 7, 8]$
  - (b) When  $i = n - 2 = 6$ :  $A[6] = 0$  and  $\text{count}[0] = 2 \Rightarrow \text{out}[2 - 1] := A[6] = 0$  and  $\text{count}[0] := 2 - 1$   
 $\text{out} = [\text{nil}, 0, \text{nil}, \text{nil}, \text{nil}, \text{nil}, 3, \text{nil}]$   
 $\text{count} = [1, 2, 4, 6, 7, 8]$
  - (c) When  $i = n - 3 = 5$ :  $A[5] = 3$  and  $\text{count}[3] = 6 \Rightarrow \text{out}[6 - 1] := A[5] = 3$  and  $\text{count}[3] := 6 - 1$   
 $\text{out} = [\text{nil}, 0, \text{nil}, \text{nil}, \text{nil}, 3, 3, \text{nil}]$   
 $\text{count} = [1, 2, 4, 5, 7, 8]$
  - (d) ...  
 $\text{out} = [0, 0, 2, 2, 3, 3, 3, 5]$   
 $\text{count} = [0, 2, 2, 4, 7, 7]$

In-place?	Stable?
False	True

Because of its use for RADIX-SORT, COUNTING-SORT must be stable, and it indeed is. If there are items with the same value, it will be moved to the *out* array in order in the last (third) for loop.

Runtime	Space Usage
$O(n + k)$	$O(n + k)$

As the algorithm iterates both the size of the array  $n$  and the maximum element in the array  $k$ , **the algorithm runs in  $O(n + k)$  time and uses  $O(n + k)$  space.**

## 3.9 Radix Sort

RADIX-SORT is a non-comparative sorting algorithm for elements with more than one significant digits. It utilizes a stable sorting algorithm such as COUNTING-SORT to sort elements lexicographically.

```

1: function RADIX-SORT(A, k)      ▷ A is an array where the maximum dimension of an element is d
2:   for i = d down to 1 do
3:       Call a stable sorting algorithm at dimension i
4:   return A

```

**3.9.1 Lexicographic Order**

$$(x_1, x_2, \dots, x_d) < (y_1, y_2, \dots, y_d) \Leftrightarrow (x_i < y_i) \vee (x_1 = y_1 \wedge (x_2, \dots, x_d) < (y_2, \dots, y_d))$$

### **6.3 BFS**

## **Chapter 7**

# **Directed Graphs**

### **7.1 Strong Connectivity**

#### **7.1.1 Brute-force Strong Connectivity Algorithm**

#### **7.1.2 Brute-force using Stack**

#### **7.1.3 Strongly Connected Components and Kosaraju's Algorithm**

### **7.2 Directed Acyclic Graphs**

#### **7.2.1 Topological Sort**

## Chapter 8

# Weighted Graphs

### 8.1 Shortest Path

#### 8.1.1 Dijkstra's Algorithm

#### 8.1.2 Bellman-Ford Algorithm

### 8.2 Articulation Points

### 8.3 Minimum Spanning Tree

#### 8.3.1 Cycle and Cut Properties

#### 8.3.2 Prim's Algorithm

### 8.4 Union-Find

#### 8.4.1 Kruskal MST Algorithm

## **Chapter 9**

# **Strings**

**9.1 Brute-force String Pattern Matching**

**9.2 KMP Algorithm**

**9.3 Trie**

**9.4 PATRICIA**

**9.5 Huffman Coding**
